

Supplement

The following supplementary materials are available for this article: Chen, T., Lee, Y.-N., Lin, P.-Y., Wu, K.-S., Zelený, D. 2024 Vegetation of *Chamaecyparis* montane cloud forest in Lalashan Forest Dynamics Plot. *Taiwania* 69(3): 399-411. doi: 10.6165/tai.2024.69.399

Extended Materials and Methods: Lalashan Saddle weather station

The standard Lalashan Saddle weather station is located in a small deforested saddle between Lalashan and Tamanshan mountains at 1730 m a.s.l. (24°43'20.9"N 121°26'31.1"E). Here, we report long-term air temperature measurements, precipitation, wind speed and direction, and visibility, measured from January 1, 2021, till December 31, 2021. Air temperature and relative humidity were measured by ATMOS 14 4-in-1 sensor housed in a sunshield (Meter, Germany). Rainfall was measured by RS-102N rain gauge (Aneos, Japan), and wind speed and direction by Young 05103 WS/WD meter (R. M. Young Company, USA). Visibility was measured by a visibility sensor MiniOFS Sensor (Optical Sensors, Sweden), using laser beam backscatter method; it quantifies the distance (in meters) to which it is possible to see an object and is used as a proxy for fog intensity. The climatic data were computed and saved in the CR300-Series Datalogger (Campbell Scientific, USA) every 10 minutes.

For the microclimatic data analysis and visualization, we applied a window-averaging algorithm with a two-hour time interval on all temperature and relative air humidity measurements. The air temperature and the precipitation were aggregated to draw a climatic diagram. The wind speed and direction were aggregated to draw a wind rose chart. The visibility was used to calculate fogginess intensity and the length of foggy time. The fogginess was classified into three categories: heavy, medium, and light, with visibility of less than 100 m, 100–500 m, and 500–1000 m, respectively. The foggy time was calculated as a percentage proportion of visibility measurements falling into the relevant category of fogginess out of all measurements done within a given month.

Table S1. Diagnostic species of the three vegetation types. Values are the relative percentage frequency (Freq.), and species are sorted by decreasing fidelity (Φ). The green colour indicates diagnostic species with a fidelity $\geq 35\%$.

| Vegetation type No. of plots | R | | E | | V | |
|---|-------|--------|-------|--------|-------|--------|
| | Freq. | Φ | Freq. | Φ | Freq. | Φ |
| <i>Daphniphyllum himalayense</i> subsp. <i>macropodum</i> | 62 | 38.1 | 30 | 33 | 17 | - |

Table S2. The multiple regression between each environmental variable and the first two DCA axes. No. subplots = in how many subplots the variable was measured; DCA1 and DCA2 = directional cosines of each variable, r^2 = coefficient of determination; P -value = significance (calculated by Monte Carlo permutation test with toroidal shift; *** = $P < 0.001$; ** = $P < 0.01$; * = $P < 0.05$; . = $P < 0.1$); No. perm. = number of permutations in the test.

| Variable | No. subplots | DCA1 | DCA2 | r^2 | P-value | No. perm. |

Table S3. Checklist of all woody species recorded within Lalashan Forest Dynamics Plot, including Latin species name with authors, Chinese species name (Chinese), family, and species abbreviation (Abbrev.). Abbreviations were created from 4 letters of genus and 4 letters of the name on the lowest taxonomic level (species, subspecies or variety), with exception of *Chamacypris formosensis* and *C. obtusa* var. *formosana*, which were abbreviated as Chamform and Chamobtu, respectively.

| Latin species name | Chinese | Family | Abbrev. |
|--|---------|------------------|-----------|
| <i>Acer kawakamii</i> Koidz. | 尖葉槭 | Aceraceae | Acerkawa |
| <i>Acer morrisoneense</i> Hayata | 臺灣紅榨槭 | Aceraceae | Acermorr |
| <i>Acer palmatum</i> var. <i>pubescens</i> Li | 臺灣掌葉槭 | Aceraceae | Acerpube |
| <i>Barthea barthei</i> (Hance ex Benth.) Krasser | 深山野牡丹 | Melastomataceae | Bartbart |
| <i>Cornus kousa</i> subsp. <i>chinensis</i> (Osborn) Q.Y.Xiang | 四照花 | Cornaceae | Bentchin |
| <i>Berberis hayatana</i> Mizush. | 早田氏小檗 | Berberidaceae | Berbhaya |
| <i>Callicarpa randaiensis</i> Hayata | 巒大紫珠 | Verbenaceae | Callrand |
| <i>Camellia brevistyla</i> (Hayata) Cohen-Stuart | 短柱山茶 | Theaceae | Camebrev |
| <i>Carpinus rankanensis</i> Hayata | 蘭邯千金榆 | Betulaceae | Carprank |
| <i>Chamaecyparis formosensis</i> Matsum. | 紅檜 | Cupressaceae | Chamform |
| <i>Chamaecyparis obtusa</i> var. <i>formosana</i> (Hayata) Hayata | 臺灣扁柏 | Cupressaceae | Chamobtu |
| <i>Cleyera japonica</i> Thunb. | 紅淡比 | Theaceae | Cleyjapo |
| <i>Daphniphyllum himalaense</i> (Benth.) Müll.Arg. subsp. <i>macropodum</i> (Miq.) T.C.Huang | 薄葉虎皮楠 | Daphniphyllaceae | Daphmacr |
| <i>Dendropanax dentiger</i> (Harms) Merr. | 臺灣樹參 | Araliaceae | Denddent |
| <i>Euonymus spraguei</i> Hayata | 刺果衛矛 | Celastraceae | Euonspra |
| <i>Eurya crenatifolia</i> (Yamam.) Kobuski | 假柃木 | Theaceae | Eurycren |

| <i>Viburnum urceolatum</i> Siebold & Zucc. | 壺花莢蒾 | Caprifoliaceae | Vibuurce |

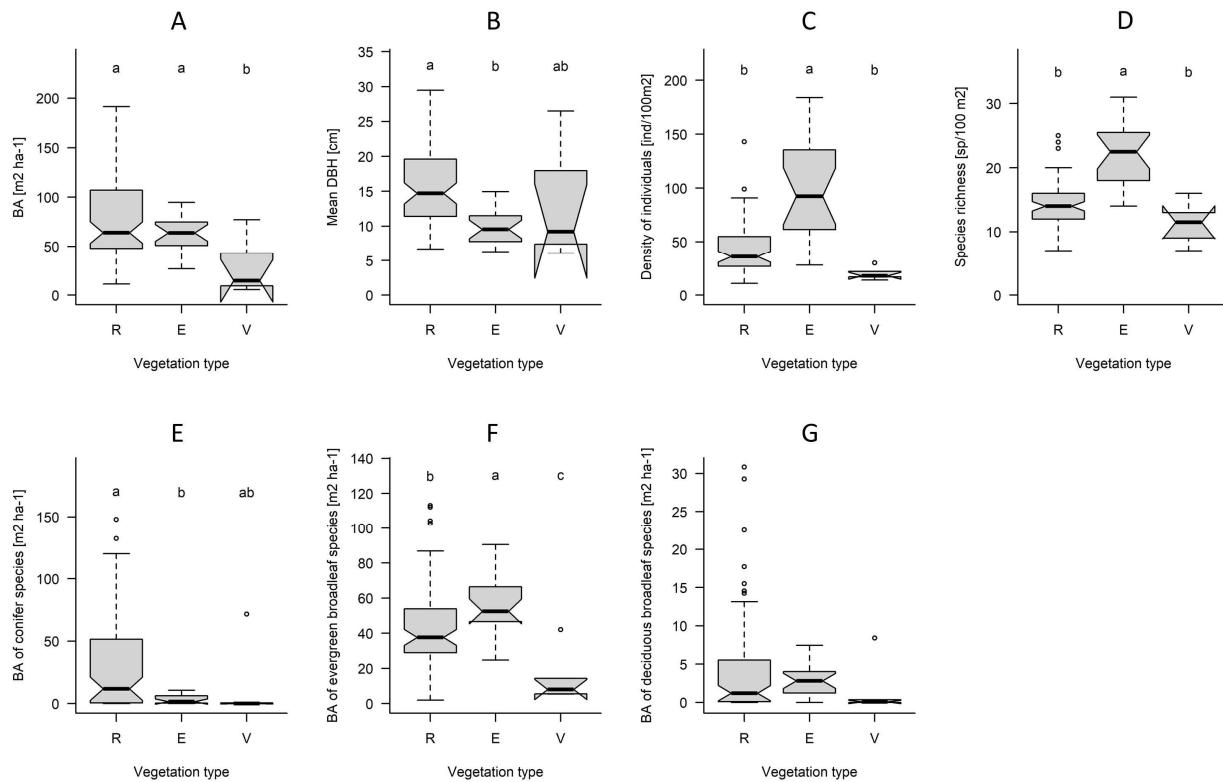

Fig. S1. Boxplots showing the subplot-based differences in vegetation structure between the three vegetation types; **A.** total BA, **B.** mean DBH, **C.** individual density, **D.** species richness, **E.** BA of conifer species, **F.** BA of evergreen broadleaf species, **G.** BA of deciduous broadleaf species. All differences between vegetation types, except for **G.**, are significant ($P < 0.05$) through the ANOVA test. R: ridge type, E: east-facing slope type, V: valley type.

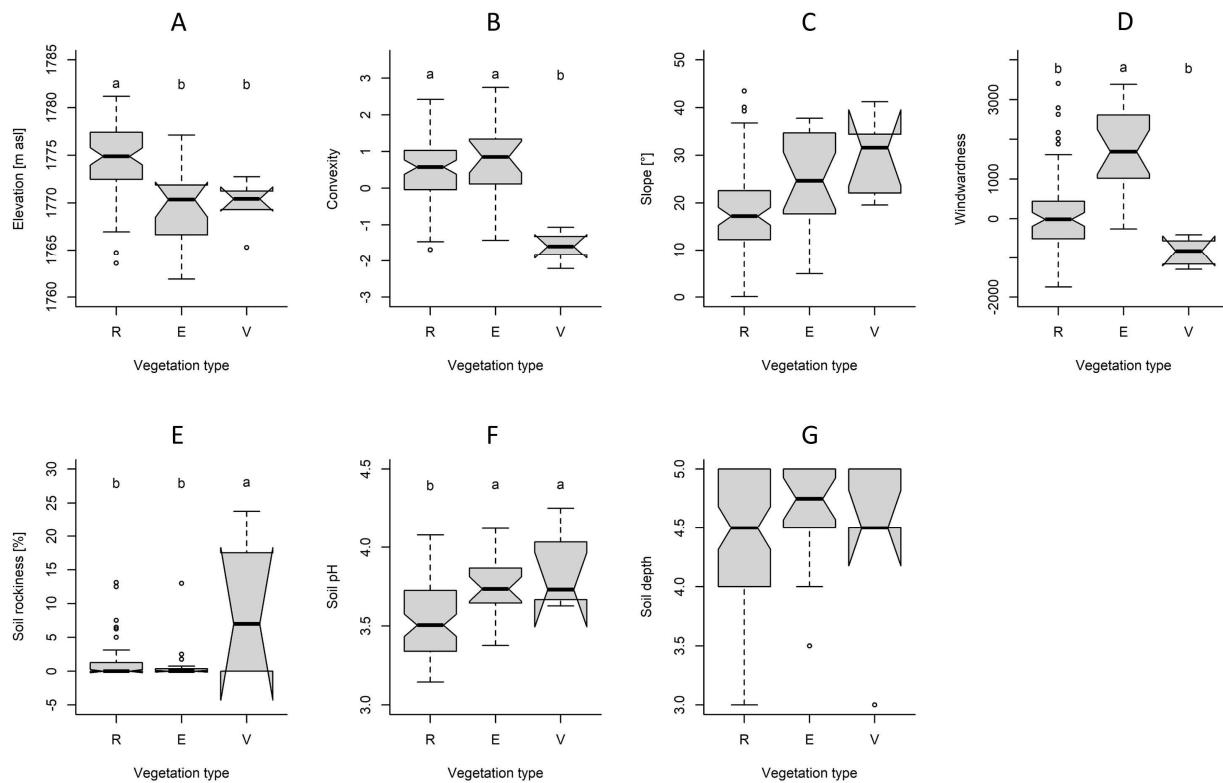

Fig. S2. Boxplots showing the differences of different environmental factors (containing 100 subplots data) between the three vegetation types; **A.** elevation, **B.** convexity, **C.** slope, **D.** windwardness, **E.** soil rockiness, **F.** soil pH, **G.** soil depth. All differences between the vegetation types, except for **G.**, are significant through ANOVA test. R: ridge type, E: east-facing slope type, V: valley type.

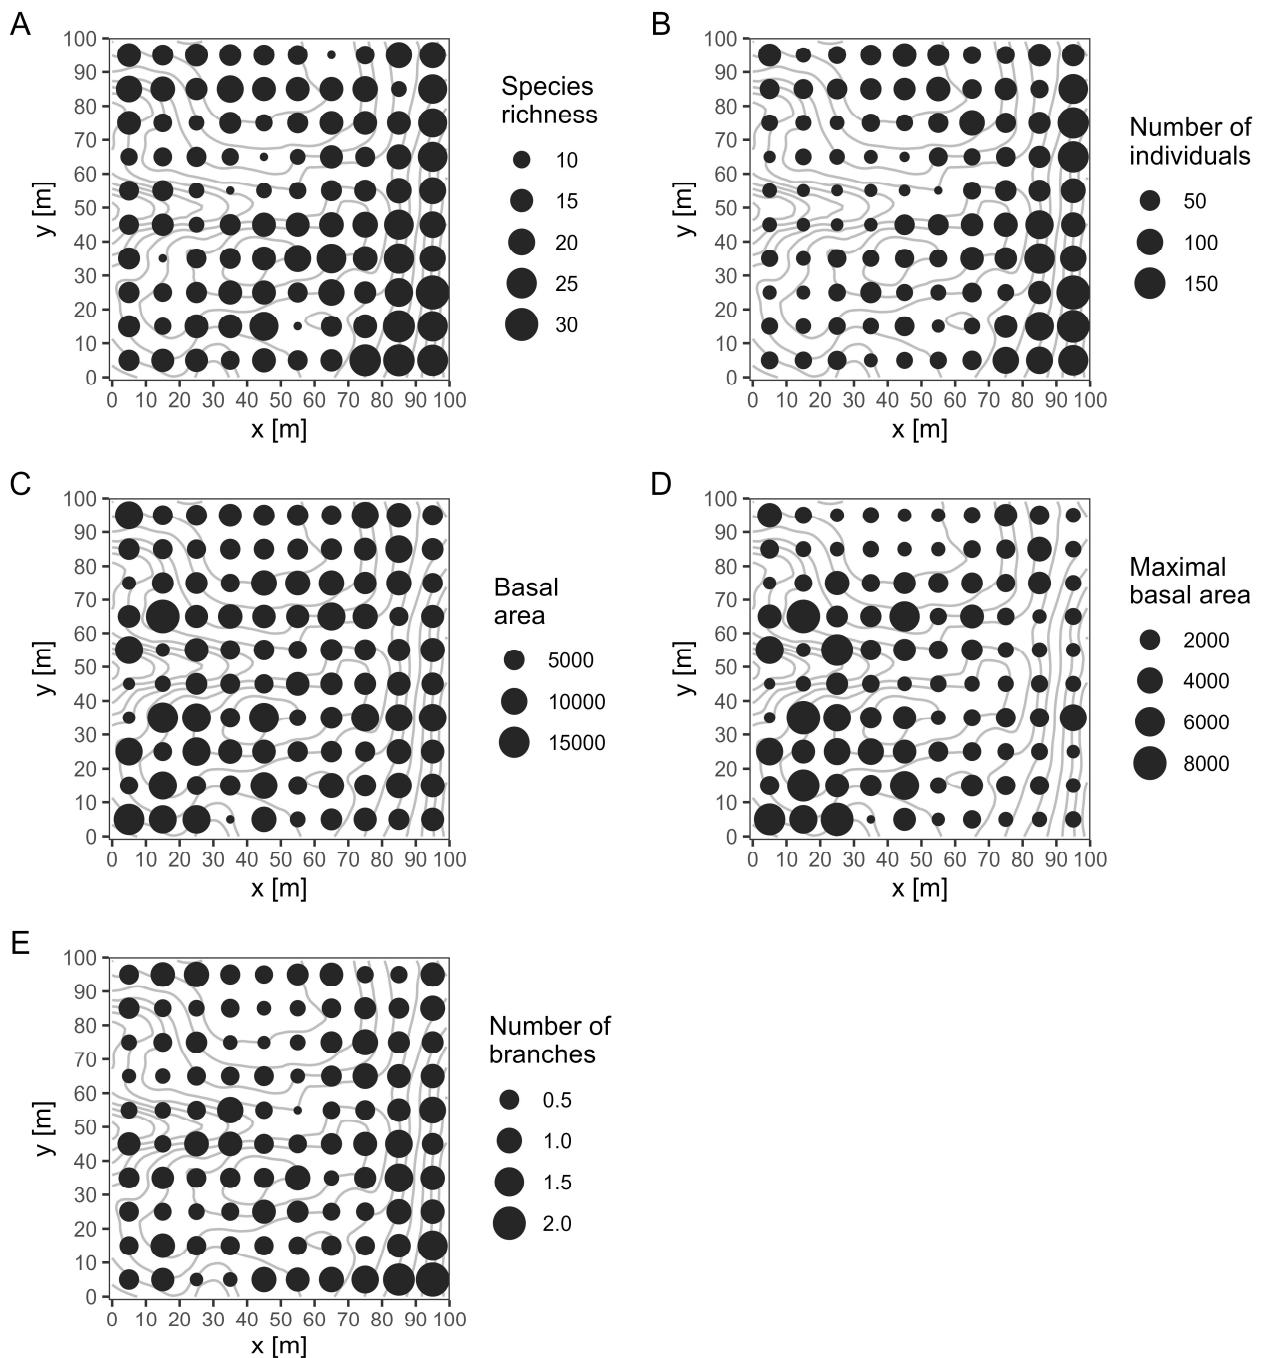

Fig. S3. Spatial distribution of **A.** species richness, **B.** number of individuals per subplot, **C.** basal area of all individuals within the subplot, **D.** maximal basal area of the largest individual within the subplot, and **E.** average number of branches per individual within subplot. The size of the circle is proportional to value of the variable in given subplot.

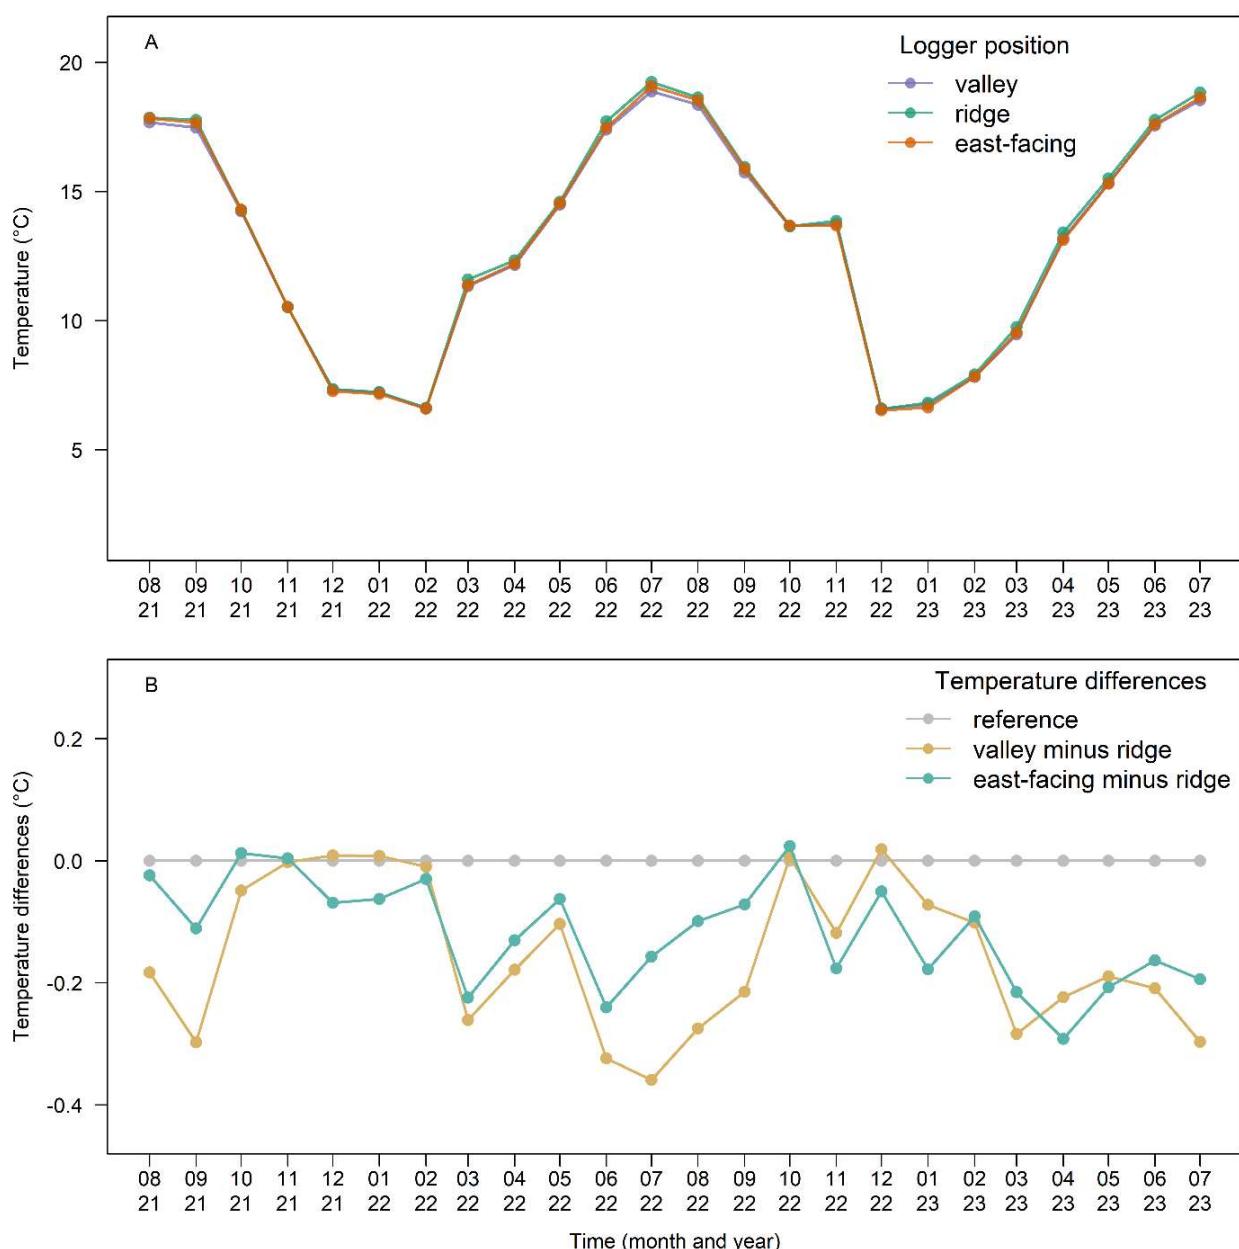

Fig. S4. The pattern of **A.** mean monthly temperature by the three loggers within LFDP, and **B.** mean monthly temperature differences between valley and ridge (green) and east-facing and ridge (blue). Reference represents the ridge logger. Data from temperature measurements between August 1, 2021, and July 31, 2023. The time x-axis is coded as month (upper number) and year (lower number).

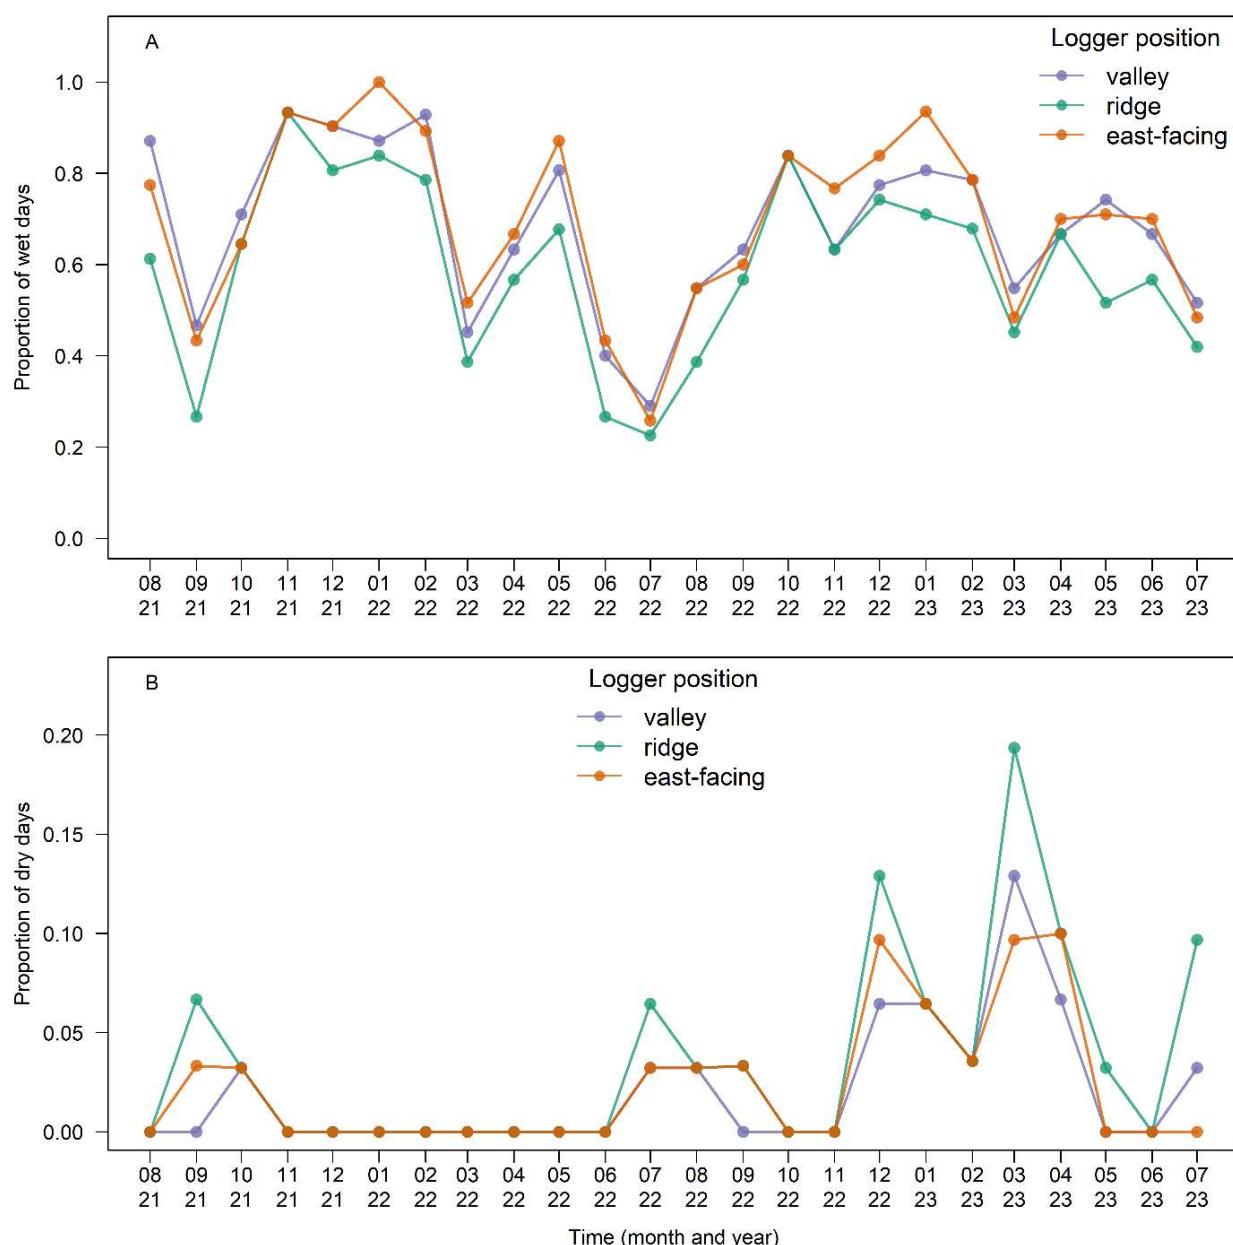

Fig. S5. Monthly proportions of **A.** wet days and **B.** dry days recorded by RH loggers located in different parts of LFDP, from August 1, 2021, to July 31, 2023. Wet days are defined as days with a mean RH $\geq 99\%$, while dry days with a mean RH $\leq 75\%$. The time x-axis is coded as month (upper number) and year (lower number).

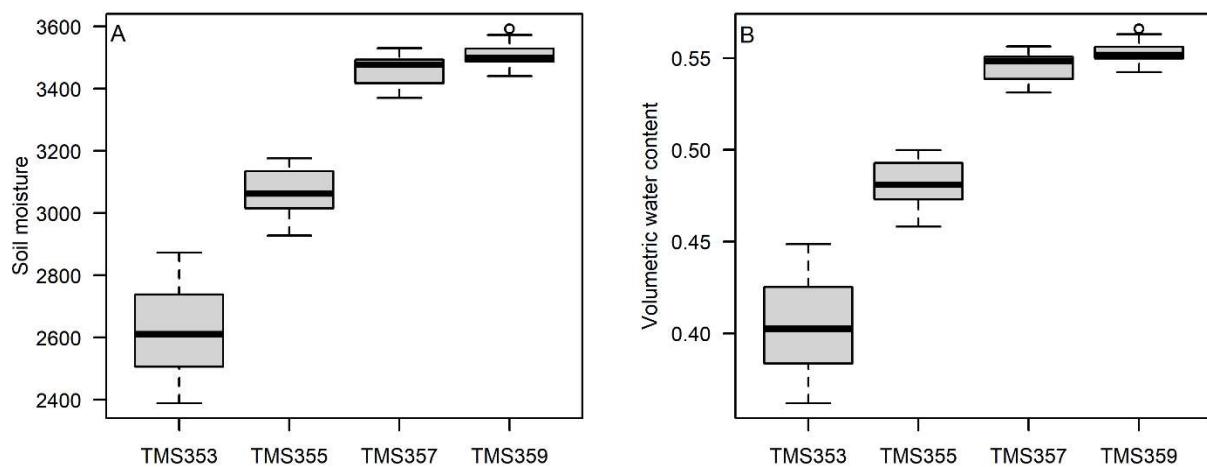

Fig. S6. Differences in **A.** soil moisture and **B.** volumetric water content along the topographical gradient from the convex ridge (TMS353) to the concave valley (TMS359), measured by TOMST TMS-4 loggers close to the centre of the plot from April 17, 2022, till May 28, 2022.

Fig. S7. Photographs of the three vegetation types in LFDP; **A.** - ridge type, **B.** - east-facing slope type, **C.** - valley type. Photo credit by Ting Chen.
